Filed: 11/12/2003

For: APPARATUS AND METHOD FOR THE INSPECTION OF OBJECTS

Honorable Commissioner for Patents
P.O. Box 1450
Alexandria, Virginia 22313-1450

DECLARATION UNDER 37 CFR 1.131

Sir:

I, the undersigned, Shmuel Rippa, hereby declare as follows:

1) I am an Applicant in the patent application identified above, and I am one of the co-inventors of the subject matter described and claimed in claims 1 – 16 therein.

2) In 1996 I joined a the ICP group of the Assignee as a software engineer on a software development team assigned to develop and implement a software system performing the functionalities described and claimed in the subject Application in systems for inspecting lead frames, and eventually ball grid array substrates, being developed at the time by the Assignee. I later advanced and became team leader of the software development team.

3) Prior to February 5, 1998, our team reduced to practice the invention described and claimed in the subject application, *inter alia*, by developing working software code that was adapted to inspect ball grid array substrates. Our team did its work in Israel, a WTO country.

4) Appendix A contains a paper that I wrote on or before October 29, 1996 entitled, "SIP Tests in Windows", and stored as a computer file under the name "sip_tests_in_windows.fm*". "SIP" is an acronym for "Software Image Processing" Appendix A is part of system

documentation for a generic model for a software defect detection package implementing the invention described and claimed in the subject application.

I have printed Appendix "A" without making any modification whatsoever to the document as stored on the Assignee's computer system. The date appearing in the header of Appendix A is automatically inserted by a date field to display the date upon which the document was printed. A screen shot of the computer directory in which Appendix A is stored is contained in Appendix B and indicates that Appendix A was last modified on October 29, 1996.

5) Appendix C contains a paper that I wrote and printed out on or before June 28, 1998. "ICP" is an acronym for "Integrated Circuit Packaging" and is the name of a project of Assignee for inspection equipment designed to inspect ball grid array substrates, a type of integrated circuit packaging. We designed ICP inspection equipment to employ software inspection as described and claimed in the subject application.

6) Appendix D contains working software code, written in the "C" programming language, implementing a task packer for assigning inspection tasks to portions of interest in an image of an electrical circuit to be inspected, as referenced in Appendices A and C.

Appendix E contains working software code, written in the "C" programming language, implementing a task manager for managing the execution of inspection tasks assigned to portions of interest by the Code in Appendix D. The software programs in Appendices D & E are part of, and run with, a suite of software programs performing defect detection during the inspection of ball grid array substrates. Other programs in the suite of programs include, without limitation, various configuration files and specific inspection tasks assigned by a task packer employing a task packer helper as in Appendix D to portions of interest for inspecting corresponding portions of an electrical circuit to be inspected.

As evidenced by the revision log appearing on page 30 et seq. of Appendix D, Version 1.1 of the code in Appendix D is dated February 18, 1997. According to our practice, only

working and reviewed versions of code were numbered. As further evidenced by the revision log, this code was regularly updated at least until February 20, 2001

As evidenced by the revision log appearing on page 15 et seq. of Appendix E, Version 1.1 of the code in Appendix E is dated October 29, 1996. According to our practice, only working and reviewed versions of code were numbered. As further evidenced by the revision log, this code was regularly updated at least until February 7, 2000.

6) The following table shows the correspondence between the elements of the system claims in the present patent application and elements of the material in appendices.

Claim 1	**Appendices**
1. An electrical circuitry inspection method comprising:	The entire document, evidenced with particularity at the illustration on page 7 of Appendix A, marked "A".
for each of a plurality of types of local characteristics, each type occurring at least once within electrical circuitry to be inspected, identifying at least one portion of interest within the electrical circuitry whereat said local characteristic is expected to occur;	The illustration on page 7 of Appendix A marked "A", the text at page 2 of Appendix A marked "B" and the text at page and the text at page 4 of Appendix A marked "C".
and inspecting an image of each portion of interest, using an inspection task selected in response to the type of local characteristic expected to occur in the portion of interest.	The text at pages 4 & 5 of Appendix A marked "D" in combination with the text at page 4 of Appendix A marked "C".
Claim 2	**Appendices**

2. A method according to claim 1, wherein said plurality of types of local characteristics includes at least one of the following types: a bonding pad; a ball structure; a target; a chip area.	The text at page 5 of Appendix C marked "E".
Claim 3	**Appendices**
3. A method according to claim 1, wherein said identifying of at least one portion of interest comprises identification of at least one spatial region within said electrical circuitry.	The illustration on page 7 of Appendix A, marked "A".
Claim 4	**Appendices**
4. A method according to claim 3, wherein said identification of at least one spatial region is at least partly based on a user input.	The text at page 4 of Appendix A marked "C".
Claim 5	**Appendices**
5. A method according to claim 3, wherein said identification of at least one spatial region is at least partly based on a computer generated input.	The text at page 4 of Appendix A marked "C".
Claim 6	**Appendices**
6. A method according to claim 4, wherein said	The text at page 4 of Appendix A marked "C".

identification of at least one spatial region is at least partly based on a computer generated input.	
Claim 7	**Appendices**
7. A method according to claim 1, and also comprising computer-assigning an inspection task to at least one individual portion of interest in response to the type of local characteristic expected to occur in the individual portion of interest.	The text at page 4 & 5 of Appendix A marked "C" and "D". Text at page 5 of Appendix C marked "F". Appendix D is software code of a task manager for assigning a type dependent inspection task to portions of interest.
Claim 8	**Appendices**
8. A method according to claim 1, and also comprising outputting at least one indication of defects responsive to said inspecting step.	Text at pages 4 & 5 of Appendix A marked "D".

5) Claims 9 - – 16 recite apparatus for inspecting electrical circuits with limitations similar to those of system claims 1-8. Based on the similarity of subject matter between the apparatus and method claims for inspecting electrical circuits, it can similarly be demonstrated that the invention recited in claims 9 –16 was conceived and reduced to practice prior to July 28, 1999.

I hereby declare that all statements made herein of my own knowledge are true and that all statements made on information and conjecture are thought to be true; and further that these statements were made with the knowledge that willful false statements and the like so made are

punishable by fine or imprisonment, or both, under Section 1001 of Title 18 of the United States Code and that such willful false statements may jeopardize the validity of the application of any patent issued thereon.

Shmuel Rippa, Citizen of Israel

Orbotech Ltd.

SIP
Tests in Windows

Shmuel Rippa

1. Requirements

"Interesting" things usualy happens at particular locations which occupies only a small portion of the panel's area. Such are the areas near errors detected by hardware (for example, line width violation report) or by software (for example, excess/missing reports), areas around morphological events (centres, open-ends, etc.) and areas around predetermined locations which we call top down events. The top down events are defined by processing of the CAM of the board or by a special learn scan.

B

In order to accelerate the computation and allow more complicated image understanding algorithms we try to restrict the computation to small rectangular regions (windows) on the panel rather than doing the computation on the entire panel. Data generated by hardware and software modules and that is inside the specified window is added to the data of the window containing the data (this procedure is called packing of the data into the window). Examples of data generated by hardware include:

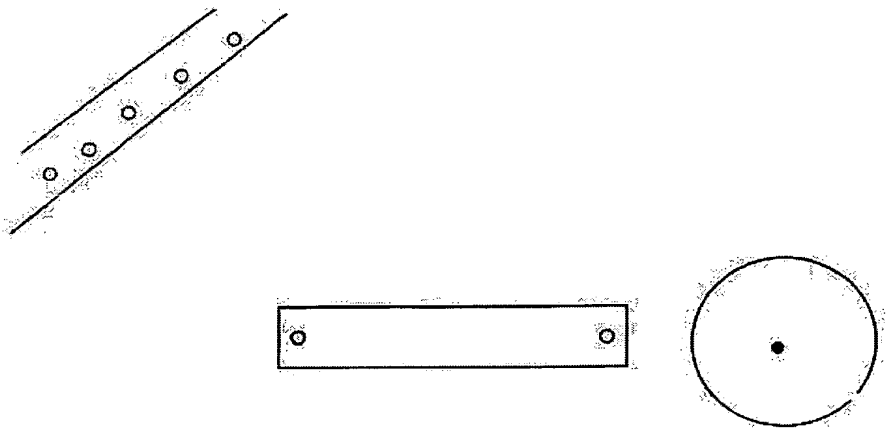
- Gray/Colour images of parts of the panel.
- CELs (Contour ELements) computed by special hardware cards.
- Morphology events (centers, open-ends, etc.) computed by hardware cards.
- More . . .

Examples of raw data genetrated by software modules include

- Excess/Missing reports
- Width violation reports.
- More . . .

Data entities are likely to be changed during the lifetime of a project as more data items are added and (perhaps) some items are removed from the above list.

In the following figure we present an example of a window containing a line segment (diagonal "fat" line), a circular shape (pad), and a rectangular shape (SMT pad) represented by CELs, two open-ends reports (displayed as dots at both ends of the SMT pad) and one center report (displayed as solid dot at the center of the circle). We also have various width violation reports (displayed as dots)on the line segment.



Data inside a window

Once the raw data is packed inside the window, it is ready to be processed by various algorithms. A typical algorithm operates on a window, uses the data inside the window and, perhaps, generates other data to be added to the data inside the window. In the following we give examples of some algorithms :

- Connected segment algorithm.
  The circle, rectangle and lines in the figure above are in fact represented by a collection of little line segments called CELs. These collections can be devided into four subsets. A CEL segment is in subset A iff it have a common point with another CEL from A. In the figure above we have four subsets : One for the circle, one for the rectangle and one for each line segment.
  Input : collection of CELS
  Output : subsets of conencted components ordered in a countercklockwise manner.
- Vectorizer
  Input : subset of connected components.
  Output : More compact representation of the subset (many little segments along a given line are replaced by a larger vector).
  Parameter: tolerance.
- Circle matcher. Match a circle in a least square sense to a set of points.
  Input : set of CELs
  Output: circle parameters.
- Shape finder. Searches for geometric enteties (circles, rectangles, lines, etc.). An algorithm should be written for each new geometric element that we wish to identify.
  Input : CELs or vectors from vectorizer.
  Output : Shape parameters.
  Parameters: Controling when the algorithm can safely declare on new shapoe.

The above algorithms can be used as basic blocks in higher level algorithms. For example an algorithm that searches for the presense of a circle will first devide all CELs into connected components. For each component the algorithm will decide either to vectorize the CELs or to leave them as is. In either case a call to circle shape finder will be made in order to check if the subset of conencted components contain a part of a circle. The algorithm will produce a list of

circles found. The algorithm also generates the subsets of connected components and the vector representation as byproducts. The total number of data items produced by higher level algorithm can not be determined in advance since it depends in the logic flow of the algorithm. There may be several algorithms for finding circles. For example if we knew that, in a specific panel, there are isolated circles and that each circle would be identified by a center report then we could device an efficient scheme that is given the set of CELs and the centre and finds the parameters of the circle around this centre.

Requirement 1 : To be able to present, graphically, each data item and all data items produced by a higher level algorithm.

Requirement 2 : To be able to select the algorithm to use, from a library of algorithms, from a configuration file and to supply parameters for the algorithm from that file. An example of such a parameter is a parameter that specifies how much CELs have to be sufficiently close to the circle that the algorithm found in order to decide that this is realy a circle.

Requirement 3 : To be able to add data items and algorithms without changing existing code.

Requirement 4 : Reusability of algorithms.

Result : We should be able to device a TCL/TK tool that displays the raw data and then allows us to select an algorithm and to specify the parameters for that algorithm. Then we apply the algorithm and can view all the data items produced by it.

nice to have : The ability to chain several simple and higher level algoriothms to form another algorithm. For example once we wrote an algorithm for finding circles and an algorithm for finding rectangles, we could create an algorithm for finding circles and rectangles. Ideally the algorithm should be implemented without the need for recompilation or relinking by using a scripting language (TCL). The scripting language should allow us to do some computations. For example checking that the centre of the circle is at a prescribed duistance from the centre of the rectangle. We want to be able to display, graphically, all data items produced by such a new algorithm.

The learning stage: In this stage we know very little about the scanned panel. We might have information that the panel is of a specific types (for example, it include only circles and rectangles). The data generated by hardware consists of CELs and features (centres and open-ends). We open a window around each feature. If the feature is a center, then we apply an algorithm that searches for a circle and if the feature is an open-end then we apply an algorithm that searches for a rectangle. The output of this stage is a reference file consisting of all circles and rectangles found in the panel. The reference may also include the original data CELs and features.

"C"

Requirement 5 : To be able to specify from a config file, the type of panel and thus the exact behaviour of the learning stage. We have to specify what algorithm to apply for each trigger and to specify what data items should be stored as reference.

The inspect stage: In this stage we are given the reference data created during the learn stage. For each ref data we attach a test function which will compare the raw data in the against the reference and decide if there is an error. The test function will be given all the

"D"

parameters required for making the comparison. For example a test for a ref data consisting of a circle might consist of computing the circle from the incoming data (CELs and features) and notify on error if the radius of the computed circle is different by more than a prescribed tolerance from the radius of the circle in the reference circle. Treatment of hardware/software errors is similar to the treatment in the learn stage.

"D"

Requirement 6: To be able to attach, from a config file, a test function for each item in the ref file and to be able to specify the parameters of the test function from the config file.

Requirement 7: To be able to view reference data agains raw data and to apply algorithms from TCL/TK tool.

2. Sipdata (sipdata.C, sipdata.H)

This is the base class for all data items used in window related algorithms. The class uses a factory (or virtual constructor) pattern, see also documentation in file sip_factory.H, so that derived classes can be added without need to change existing code. Each object derived from Sipdata have a type which is the name of the derived class and a name which uniquely identifies the object among many objects of the same type. The function `SetName` allows to set a name of a `Sipdata` object while the function `Name` returns that name. The base class Sipdata do not have a default constructor. It is necessary to specify a name for the object when constructing it. The Sipdata base class provides two more public methods, `Read` and `Write` for reading and writing of `Sipdata` objects. The `Write` method use `Io_util` object to write data in ASCII or binary forms. It writes the name of the derived class and then call `DoWrite` to let derived class do the rest of the job.Reads object from file in ascii or binary mode. The `Read` method function will be called after the calling program have read the line in the file containing the name of the derived class and called the `DoCreate` function to create an instance of the derived object. That `Read` method of that object is then invoked. Calls virtual `DoRead` function to do the actual reading.

Deriving from Sipdata.

In order to derive from Sipdata it is necessary to defined the following virtual functions:

- `Index`.
  The factory pattern requires that the base class will manage a table with an entry for each derived class. Index returns the index of the derived class of a specific object in that table.
- Type.
  Returns the name of the derived class.
- `DoCreate`.
  Allocate a new object from derived class and returns a (base class_ pointer to it
- `Display`
  Use a Display_data object to display graphically the concrete data of derived class.
- `Erase`
  Clears all data and leaves an empty object.
- `DoWrite`. Used by public method `Write` of base class.
  Writes object using `Io_util` object in ascii or binary mode. W
- `DoRead`
  Reads object written by `DoWrite` from file in ascii or binary mode.

The base class was designed so that it is possible to add new derived class in a very simple way

and without changing the code that is responsible for creation of derived objects stored in a file. To derive a class one have to folllow the instructions in `sipdata.H` file. Then all that is needed is to link the new code with the application.

Subclasses that have been derived so far are

Table 1: Subclassed derived from Sipdata

File names	Description
sipdata_cel_events.C sipdata_cel_events.H	collection of CELs
sipdata_feature_events.C sipdata_feature_events.H	collection of features
sipdata_connected_components.C sipdata_connected_components.H	conencted components decomposition of CELs
sipdata_isolated_circles.C sipdata_isolated_circles.H	All circles defined by a single, closed, connected component.

3. Rect_win (rect_win.H) , Sipwin (sipwin.C and sipwin.H) , Sipwin_file_of (sipwin_file_of.C and sipwin_file_of.H)

A `Rect_win` structure defining a rectangular window by specifying its endpoints `x0`, `y0`, `x1` and `y1` and its "hot point" (`xh`, `sub_pixel_x`), (`yh`, `sub_pixel_y`) with is given in sdubpixel coordinates. The class `Sipwin` is derived from `Rect_win` and is used as a container for `Sipdata` objects .

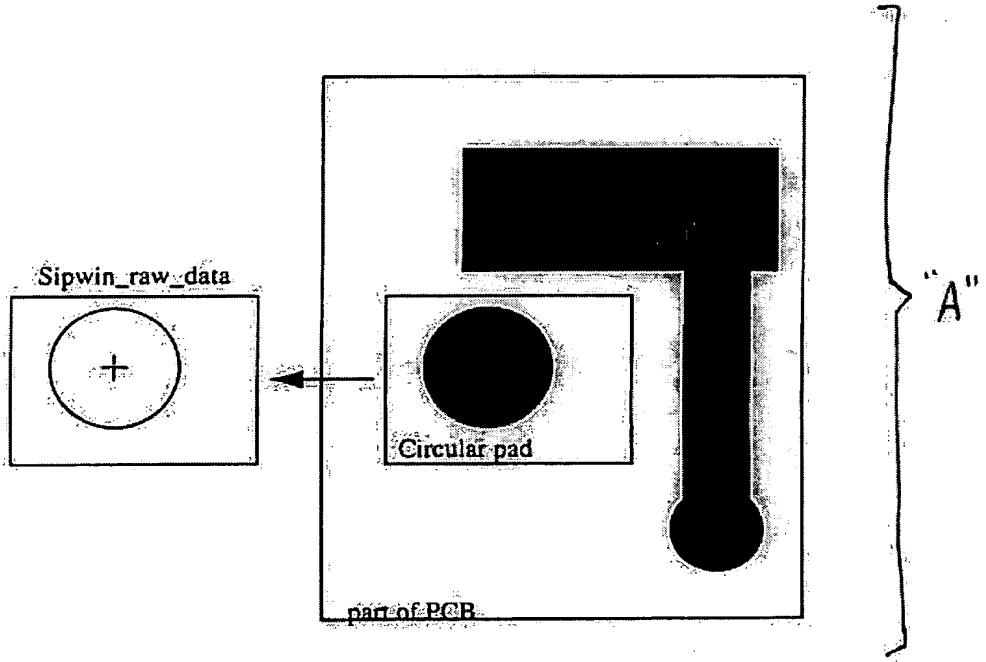
Th public methods of `Sipwin` are:

- `Put( const Sipdata * s)`.
  Put `s` in `Sipwin`. This represents a transfer of ownership from the caller to the window. The `Sipdata` object `s` is given a `const` attribute.
- `PutNonConst( const Sipdata * s )`
  The same as `Put` but `s` is given a non `const` attribute.
- `const Sipdata * Withdraw( int i )`
  `const Sipdata * Withdraw( const char * name )`
  Take an element out from `Sipwin`. This represents a transfer of ownership from `Sipwin` to the caller. The element can be retrieved by its index or by its name. If element not found or if it was found but its attribute is non `const`, then the method returns NULL. In addition we have two methods for taking non `const` elements out of Sipwin. These methods return NULL if element not found or if it was found but its attribute is `const`:
  `Sipdata * WithdrawNonConst( int i )`
  `Sipdata * WithdrawNonConst(const char * name )`
- `const Sipdata * Get( int i )`
  `const Sipdata * Get( const char * name )`
  Get an element from `Sipwin`. The element can be retrieved by its index or by its name. If element not found or if it was found but its attribute is non `const`, then the method returns NULL. In addition we have two methods for getting non `const` elements out of `Sipwin`. These methods return NULL if element not found or if it was found but its attribute is

```
const:
Sipdata * GetNonConst( int i )
Sipdata * GetNonConst(const char * name )
Read.
```
Reads object from file in ASCII or binary form.
```
Write.
```
Writes object to file in ASCII or binary form.
```
Display.
```
Use Display_data object to display graphically the data inside the window.

The `Sipwin_file_of` class is responsible for reading and writing files containing `Sipwindows` from and into files. A file containing collection of `Sipwin` objects can be openned for reading or writing by using the `Open` method. The file can be closed using the `Close` method. The `NumberOfSipDataObjects` method returns the number of `Sipwin` objects in the file. The `Write` method appends a `Sipwin` object to the file and the `Read( int i )` method reads the i'th `Sipwin` object from the file.

The `Sipwin_vector_of` handles a vector containing many `Sipwin_data` elements which are stored in memory. The class provides methods for reading/writing from file (using the `Sipwin_file_of` class) and for fast random access to its entries.



3.1 `Sipwinfunc`, and `Sipwin_vector_of_functions`.

This is the base class for all functions that work on Sipwindows. The class uses a factory (or

virtual constructor) pattern, see also documentation in file sip_factory.H, so that derived classes can be added without need to change existing code. Each object derived from `Sipwinfunc` have a type which is the name of the derived class and a name which uniquely identifies the object among many objects of the same type. The function `SetName` allows to set a name of a `Sipdata` object while the function Name returns that name. The base class `Sipwinfunc` do not have a default constructor. It is necessary to specify a name for the object when constructing it.

Each concrete function contains parameters controling its behaviour. For example, a function that checks circular pad have a parameter specifying the max allowed difference between the radius of the computed pad and the radius of the expected pad. The function will be called with a Sipwin object containing a reference circle and the CELs inside the window. The function will try to fit a circle to given CELs and reports on defect the computed radius is smaller that the expected radius minus tolerance or larger that the expected radius plus tolerance. The function will compute a description of the computed circle and add it to the data of Sipwin.p The base class will contain the following public virtual functions:

- `Type`.
  Returns the name of the derived class.
- `DoCreate`.
  Allocate a derived class object as a pointer to Sipwinfunc.
- `SetParams`.
  Sets parameters for the function from a configuration object. NOte: Each concrete function will have another, overl;oaded, version of SetParams for explicitly setting the parameters for that function.
- `Execute`.
  Perform the computation of the function given a `Sipwin` function as input. Output of computation will be added to this `Sipwin` object.

The class **`Sipwinfunc_vector_of`** is responsible to read a set of functions defined in a configuration file to provide access to the functions etc.

4. Top down methodology, Sipwin top down_reference, `TopDown` data item, top down `Sip_event`, and `TopDown task` and the class `Sipwin_top_down_tests`

The top down methodology is based on constructing a reference describing the entities to be checked. The reference contains information about the entity (for example, A circular pad of radius of 30 MIL is expected in a given location) and about the test that is to be performed (check that the radius of the pad is not smaller that 25 MIL and not larger than 37 MIL.) The creation of a top down reference is very important and may be a difficult task. The reference may be created using accurate CAM data, or it may be learned from a special learn scans. Once a good top down reference is available, it can help considerably to increase the detection and to decrease the amount of false alarms.

The top down reference consists of three files :

- A file containing `Sipwin_data` objects. This file is created by a special learn scan or by processing of CAM data.
- A file containing definiitions of all functions used in the scan with their parameters. For example, if we want to fit circle to CELs with two tolerances then we will have two function definitions in the file.

A file containing a list of function names. The i'th entry in that file contains the name of the function that should be attached to the i'th window from the window file.

A `TopDownReport` data item consists 32 bits devided as follows:

A `Top_down_event` class is derived from `Sip_event` class and contains a single `TopDownReport` object.

The TopDown task loads the top down reference and is responsible for producing the top down data source. If the task works without registration than the TopDown data source consists of top down events which will allow access to the top down table. If there is a registration then the task transform the top down reference from reference coordinates to on-line coordinates and produce the top down data source.

The class `Sipwin_top_down_reference` contains the complete top down reference which consists of a vector of Sipwin_test_raw objects, a vector of Sipwin_test_compound objects, a referenbce table and a top down data source.

The class provides the following public methods

- `LoadConfiguration`.
  -- Use `Sipwin_vector_of` method to load all windows in the file of Sipwindows.
  -- Use `Sipwinfunc_vector_of` to load all functions, with their parameters, from file of functions.
  -- Run over file of function names. Build a vector of pointers to `Sipwinfunc` objects from `Sipwinfunc_vector_of` such that the i'th entry corersponds to the function assotiated with the i'th `Sipwindow`.
  -- Construct a full `Ds_array<Top_down_events>`.
  -- Consider Meta windows. Meta window is a windor that contains data produced by functions operating on other windows. The meta window hirarchy is determined when learning the board. We define to each window, its consumers (if any) and build a data srtucture for defining the consumers of the data produced by the top down function operating on each window. In the meta window itself we shall store information on how many data items it uses.
- `Clear`. Undo LoadConfiguration.
- `Yiterator`.
  Returns iterator to the y'th line of `Ds_array<Top_down_events>`.
- `Sipwinpack * HandleTrigger(const Top_down_event & trigger)`
  The trigger is a top down event , we get the index of the corresponding (the index element of the top down item) Sipwin element in Sipwin_vector_of. The coordinates of ????? its window are transformed from the reference coordinate system to the on-line system.
  Returns NULL on error.

5. Sipwin_trigger_handler

This class is for handling triggers. It consist of the following public methods:

- `LoadConfiguration`.
  Load all information needed for computation.
- `Clear`. Undo LoadConfiguration.
- `Sipwinpack * HandleTrigger(const Sipwin_top_down_reference & td_ref, const Sip_event * trigger)`
  If the trigger is a top down event ,call `td_ref.HandleTrigger( Top_down_event *)trigger )`. In any other case, use internal logic to create and return required data.

6. Sipwinpack

The class `Sipwinpack` helps that packer program to get information on window in wich data is packed and provide push_back functions to add packed items into Sipdata containers.

The class provides the folowing public methods:

- `Sipwinpack( int x0 int y0, int x1 int y1 )`
- IsOk()
- Win()
- push_back(...)
- NotifyAllFeaturesPacked
- NotifyAllCelsPacked

7. Top_down_ task

Is attached to transformation data source and to static top down reference data source. Produces data source of top down events after transformation and ordering of top down events in online liens. Produces alligned top down events.

8. Packer task

Attached to data sources that produce triggers, to top down data source, to cel data source to static top down reference data source and to stating trigger handler data source. Produces queue of windows data source.

The task puts all trigger data into Sip_event lists ordered by priority. Then call trigger handler for each trigger that is not inside existing window. Gets pointers to Sipwinpack objects that are inserted into list of overlapping windows. Packe triggers, data sources and CELs inside Sipwinpack objects containing them. After pack is completed, notify the Sipwinpack object on end of packing and push packed window into queue.

9. test manager task

Uses win_queue data source and static top down reference data source. It pops window from queue, execute the corresponding function and distribute results to costumers. Process defects

if found and push new test into queue if neccessary.

10. Sip_defect and Sip_vector_of_defects

This class will contain description of defects detected during scan. The class is TBD. Probably it will consist of the following

- version number (static attribute of the class)
- on-line --> reference registration (Identity for learn scans)
- Location (x,y) in on-line coordinate system.
- TCL string describing the defect.

The class will provide the following public methods:

- Read/Write to and from file in TCL forms.
- Set/Get for all non static elements.

The class `Sip_vector_of_defects` will allow read/write of TCL file containing defects and provides iterator to all defects.

Orbotech Ltd.

SIP ICP

scenarios

Shmuel Rippa

1. Introduction

In the following we present the SIP scenarios we have in the SIP implementation for the ICP (BGA) machine. We will refer to two subsystems:

- Version I.: The system that we suggest for Sept. 1998.
  Main method of inspection is CEL2VEC for all areas but the Balls area. The inspect will be based on CEL2VEC comparison of reference against online panel without any handling of hardware defects (nick/protrusions), excess/missing or line width defects. The reference created will be as follows:
  -- Front side. Reference consist of Balls, Pads and Voltage lines areas. The reference for Balls consist of description of balls and other references consist of vectorized connected components. Reference will be made for slice 1 (the central camera) only. During the preparation of the reference we shall encode inside the vectorized data also information of different zones (critical Vs noncritical) using the clipping and polyline ID. mechanism.
  -- Rear side. Reference consists of Balls. The reference will consist of the description of the balls. Reference will be made from all slices, transformed by the cameras transformation into one reference system and stored.
  In this version we will not support serious handling of design rule errors. We will not create mask areas and will not filter features inside those areas, by using a full blown filter task. We may wish to define areas to filter and filter out defects falling in those areas by a simlistice algorithm. T
- Version II.
  We will try to make inspection in small areas of interest (ROI) consisting of pads (a window pre pad). The inspection of pads will include (in addition or replacing the CEL2VEC) computation also determining changes in line width of the pad. The Balls area and volatge lines remain as in version I. We shall add to the inspect also windows triggeres by hardware defects, excess/missing and line width defects. The reference for Balls (including the reference for the rear part) and voltage lines will be as in version I. Reference for Pads will be in the form of a window per pad. The reference may incude in addition to vectorized form of the pad also information about width (say, the skeleton of the pad) of the pad. We will have to add a mechanism to corerctly assign tolerances of tests to windows created for defects (nick/protrusions, EM and line width) with respect to their position (critical, non critical etc.).

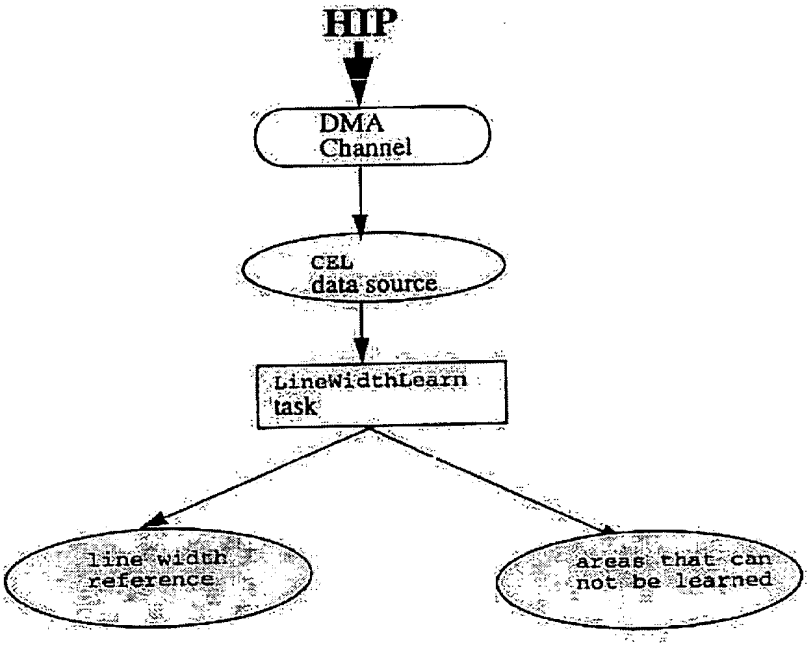
2. Learn line width scenario.

will be used for front side only.

2.1 Version I.

No need for this scenario unless we want to include desing rule errors including min space or min line width.

2.2 Version II



Learn Line Width scenarion

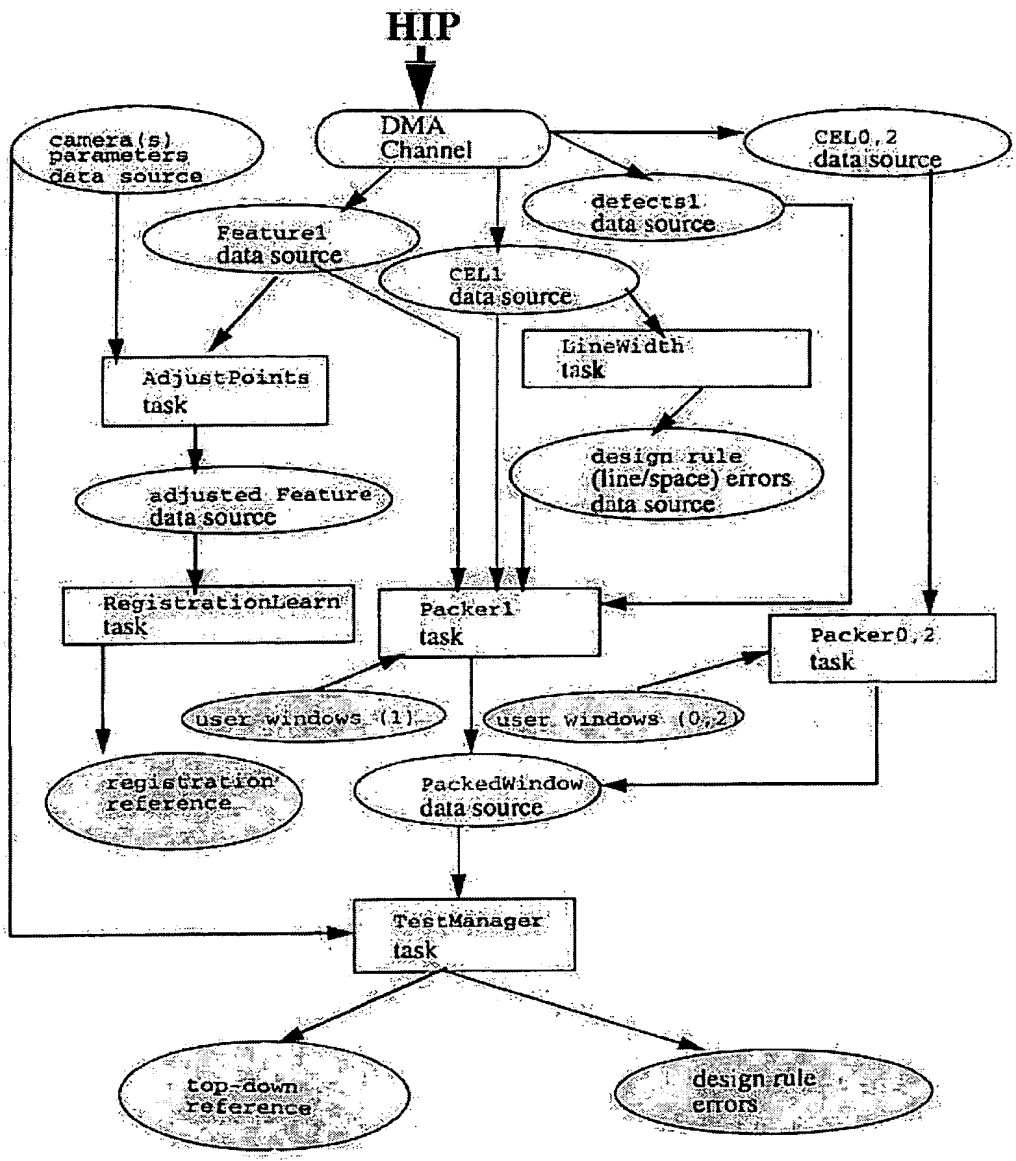
The **LineWidthLearn** task process all CELs and skeleton reports that are used to measure the line width of all "lines" (say, black areas). The line width reference is composed of a set of rectangles. Each rectangle encloses an area on which all line width mesurments had approximately of the same value. In areas of the panel where the widthes of the lines change too much, it is not possible to create a suitable line width reference. The LineWidthLearn task identifies those regions and encloses them in rectangular areas which are produces as areas than can not be learned.

QUESTION - do we want to produce design rule defects? (reduction below min line widh or min space violation?)

3. Learn top down and registration - front side

We shall work on data coming from the central camera only.

3.1 Version I.



CELi : Cels for slice (camera) number i.
Featurei : Features for slice number i.
defectsi : Hardware defects (nick/protrusions) for slice i

camera(s) parameters data source. Provides access to camera(s) parameters. The information includes number of cameras (slices). For each camera we provide the camera lenght

(number of diodes), and an affine transformation that transforms the camera coordinate system into an ideal (mathematical) reference coordinate system.

AdjustPoints task- Takes point data sources (for example, features and defects). Applies the camera transformation and produces the points in the ideal coordinate system. The input to the task may include features (or defects) on more than one slice,. The output is always a single (unsliced) data source. When processing data from more than one slice, the task also eliminates multiply features that are defined on more than one slice on the overlapping area.

RegistrationLearn task- Just takes all features in the ideal coordinate system and store them in the learn reference. If we want to learn only stable features then we must produce these stable features (for example, by the stp top down reference function) and feed them to the registration task (this means that we have to create a new data source of stablke events that are consumed by the RegistrationLearn task). Alternatively, we can get read of this task and produce the stable features directly into the registration reference.

LineWidth task. Measures line and space violations agains fixed line and space criterion. Any violation is reported as line width defect.

AdjustPoints task. Gets the camera parameters. Transform the input (online) features to the ideal coordinate system. Produces transformed features. When the inpout inclides points on more than one slice

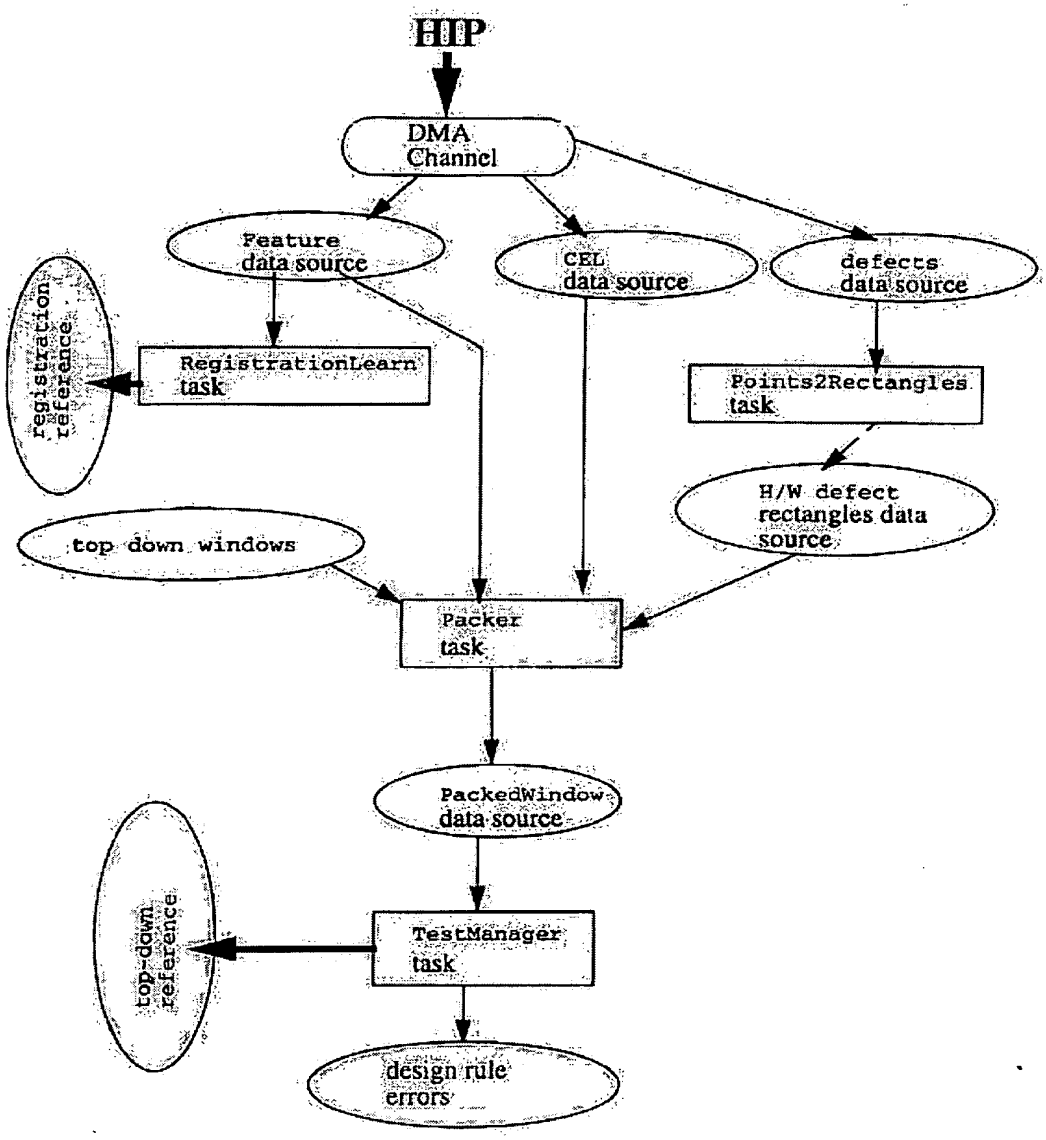
top down windows. consists of
- Balls (user defined). The balls areas.
- Pad areas.
- Voltage lines areas ?
- target areas ?

"E"

PackerTask. Gets one or more rectangles data sources (examples are top down rectangles, width disqualified windows and the rectangles data sources of defects). Applies a simple priority mechanism to dissolve inclusion problems (what i f defect/width disqualified rectangles are included inside top does rectangles, then they are packed inside the top down rectangles). If defect rectangles are found inside disqualified width windows they are packed inside them. All CELs and features are packed inside the requested windows. top down windows and the defect windows that do not fall inside existing top down windows. After windows are packed they are pushed into queue of windows.

TestManager task. Pops widnows from the queue and executed the requested test function that depends on the name of the window:
- Balls. The window is assumed to be composed only of circles where each circle is a single closed connencted component. Design rule checks are performed to ensure that the circles are within permitetd radiuses. Creates a reference of circles.
  Q : What about balls in rear seen by several slices?
  Q : What to do with defect windows found.
- Pad. Determening the critical areas, creating a reference of compressed polygons suitable for CEL2CEL type comparisons. The compressed polygons wil be determined in "large" windows consisting of all user defined windows (pads and voltage lines).
  Q : What to do with defect windows found inside top down windows.

"F"



3.2 Version II.

We shall add to the top down windows also the list of all disqualified windows (that is, windows for which we can not create a line width reference). The test manager task will contain a different function for creating reference for pads. This time we create small reference windows, one around each pad. We need to make sure that the reference windows will allow proper handling of micro registration task. The reference for disqualified width windows will consist of all compressed polygons suitable for CEL2VEC type comparisons.

Q: What to do with defect windows found inside disqualified windows or when disqualified widnows are interscctcd with other top down windows (balls, pads, voltage lines).

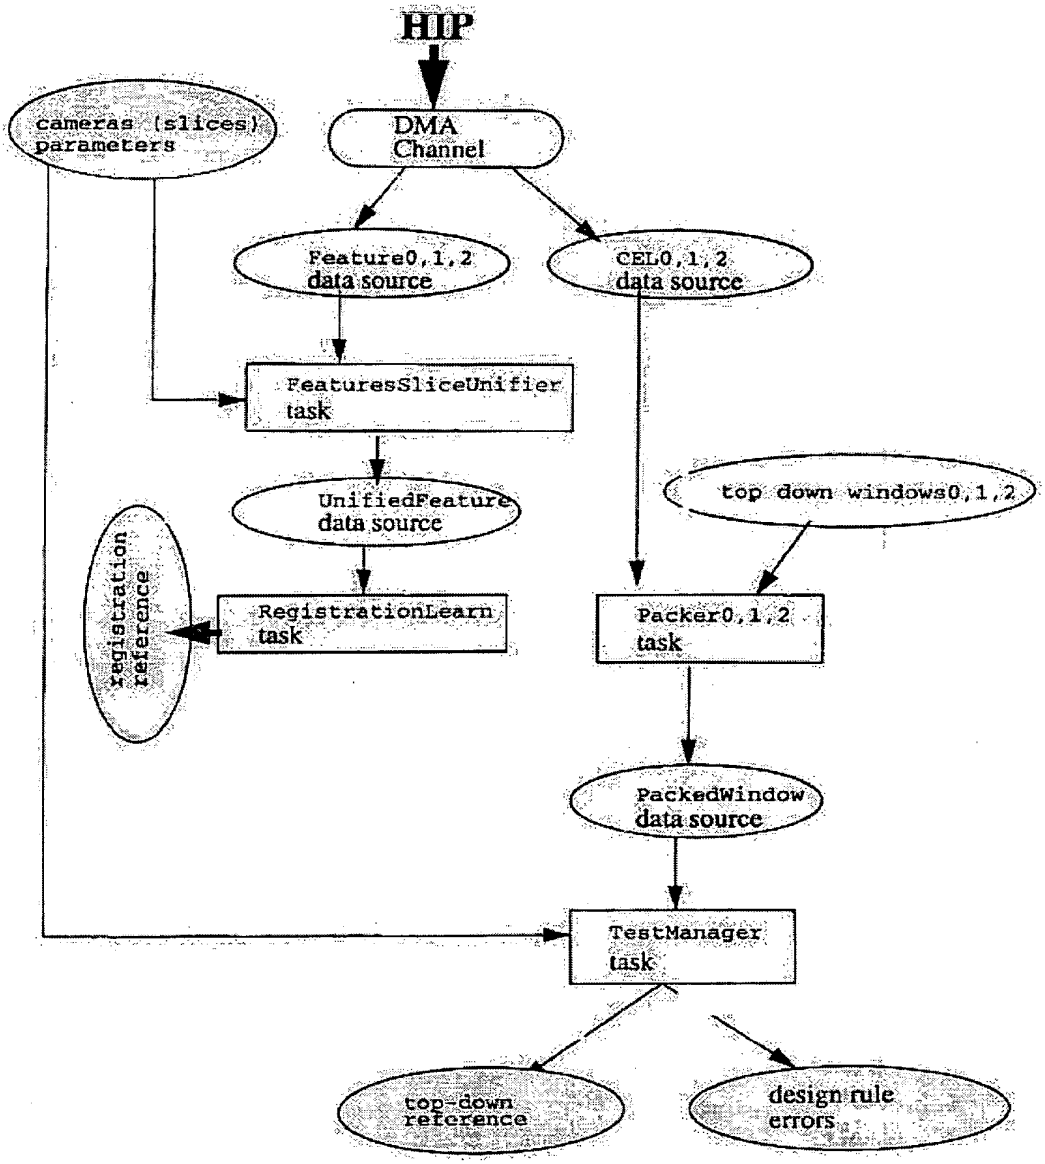
Points2Rectangles. This task consumes data sources consisting of points. It uses some clustering mechanism to group thos points into rectangles stored in *rectangles data source*.

rectangles data source. A data source for rectangles. In order to be able to put a rectangle into this data source, the rectangles should be synamically allocated and point to an object derived from *TypedRectangle* class. A *SmartPtr* to this object will be inserted into the *ds_array* data source. Line Yof this data source will consist of all rectangles of the form [x0,y0] X [x0,Y].

ds_line_collection. This data source is pretty similar to ds_array data source. Th edifefrence is that on any line it store not an array of elements ordered by their x coordinate but a collection of items, not neccessarily ordered. We use push_back operations to insert elements, one by one into the line. We begin the insertion by calling to the comamnd BeginLine() and end it by the method EndLine().

4. Learn top down and registration - back side

4.1 Version I + II



In this scenario we have to handle information coming from three cameras. Each camera is feaded to the hardware which produces slice based data (features, CELs, etc.). We hane the *cameras parameters*, that include affine transformations of each camera into one unified coordinate system and information on cameras overlap. We assume that the cameras overlap is larger that the diameter of the largest expected ball. Thre are three data sources for features

(fearure0 for features on first slice, ,feature1 for features on second slice and feature2 for features on third slice , or, in short feature0,1,2) and three data sources fo CELs (CELS0,1,2).

Task *FeaturesSliceUnifier* Takes features from all slices and produce a feature data source on which features are defined by the unified coordinate system. This task takes into account the cameras overlap and merge multiply features detected in two adjacent slices.

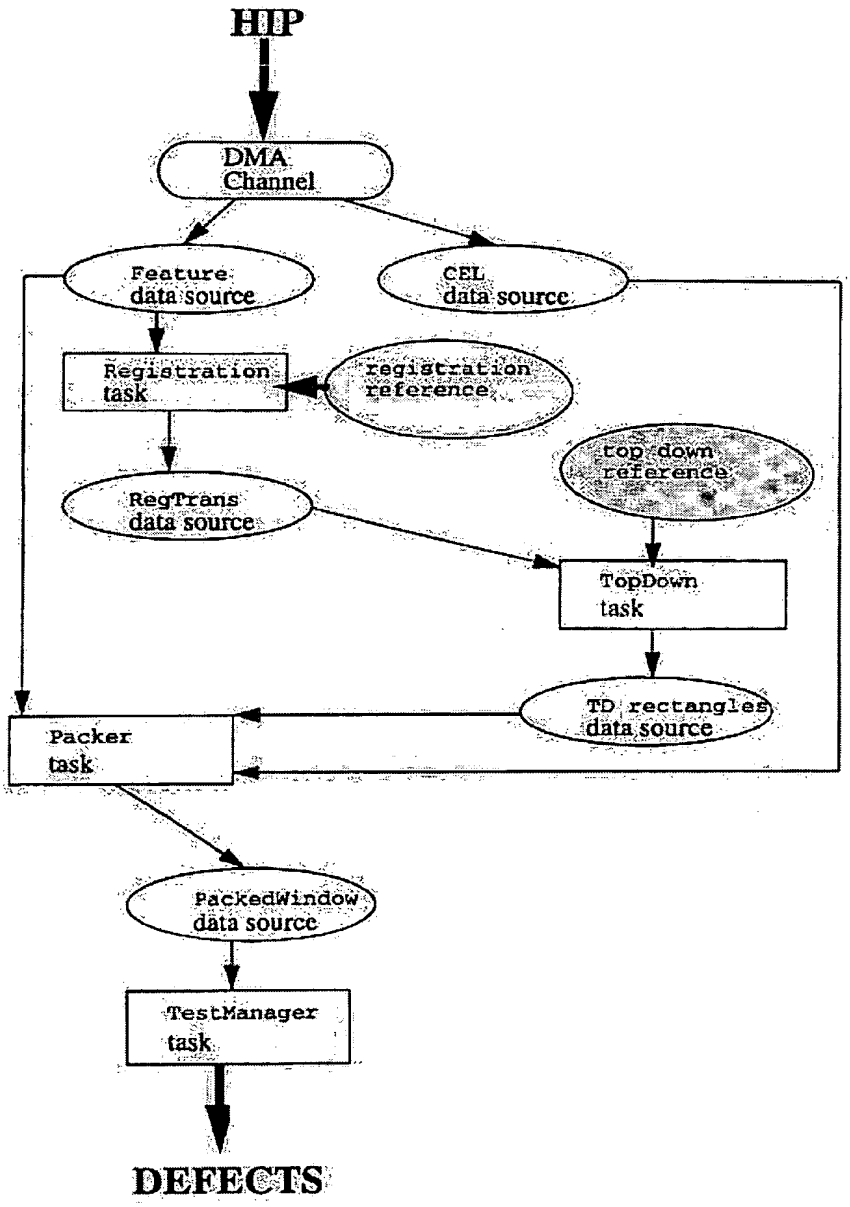
Top down windows include only balls. There are three top down windows of type Balls, one for each slice.

There are three packr tasks, each accepting data from different slice. All packed windows are pushed into one queue The function in test manager task produces one topdown reference on the unified coordinate system after merging multiply balls (falling in two adjacent slices).

5. Inspect execution graph - front side.

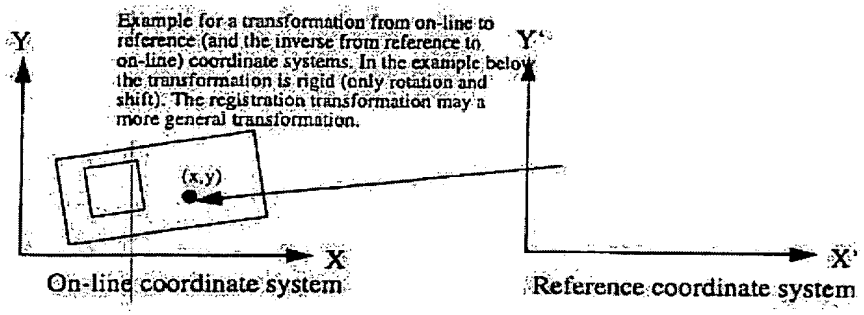
working on central slice only.

5.1 Version I.



Registration task (inspect). Uses features to compute the registration transformation. The transformation maps points from the on-line coordinate system to the reference coordinate system. The registration module also identifies reference features not found in the set of on-line features as missing and on-line features not found in the set of reference features as excess. Excess/missing features are reported as EM defect.

Inspect execution graph - front side.



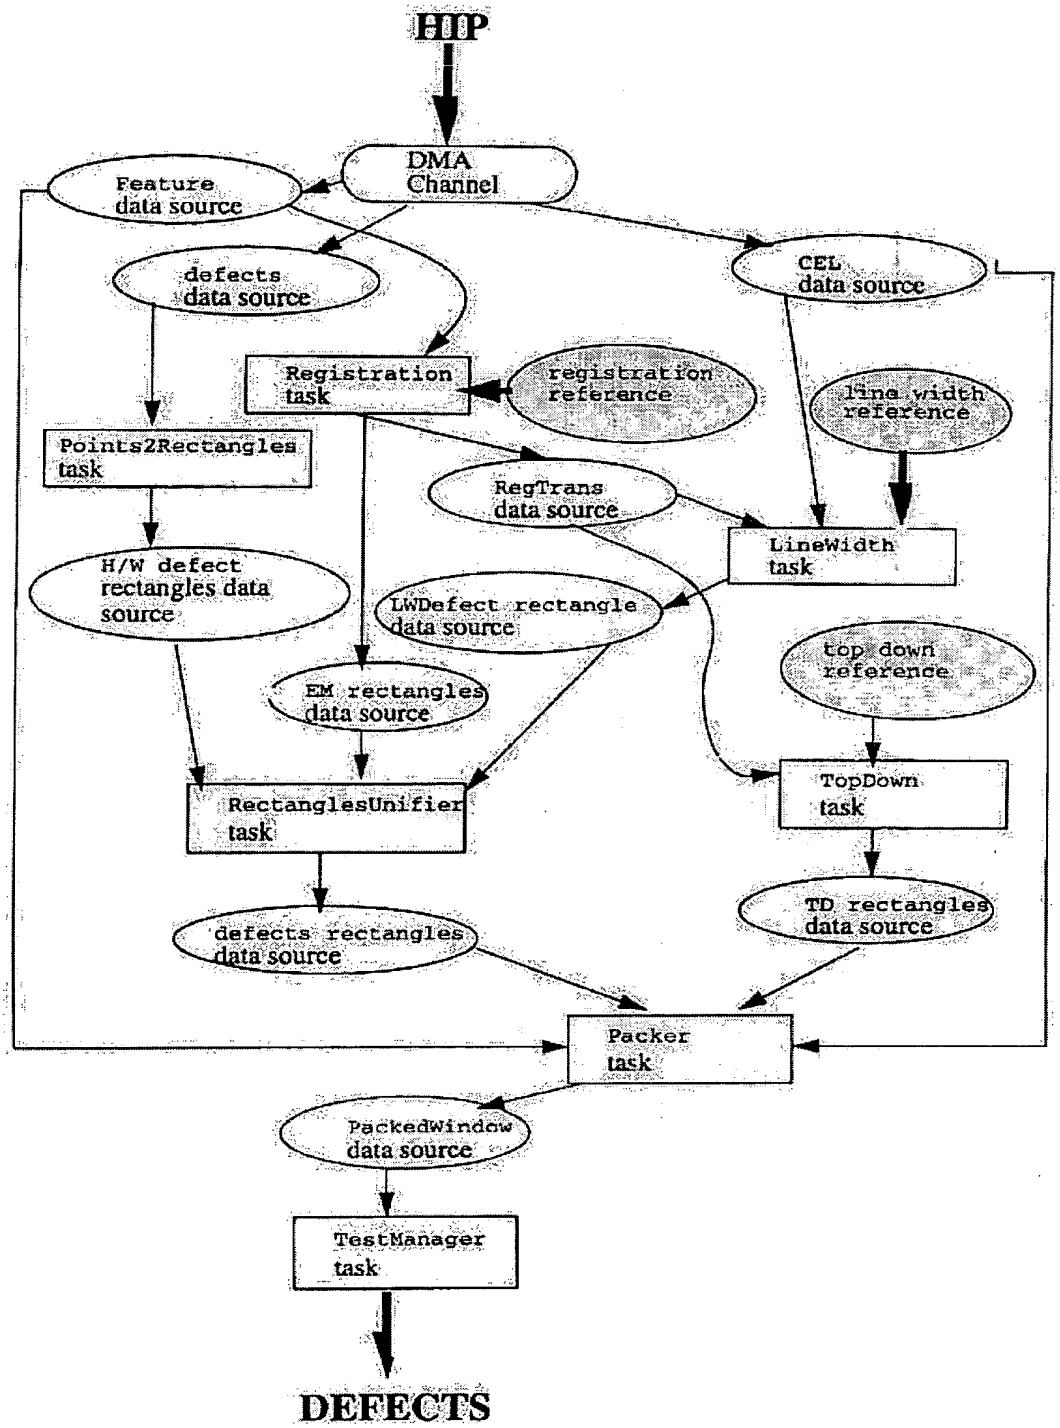
RegTrans data source. A data source that returns for each line y the most appropriate registration transformation for that line.

TopDown task. This task applies the registration transformation to the top down reference (defined in reference coordinate system). It sort transformed trop down windows according to their largest Y coordinate and puts all windows that ends on specified Y coordinate into a rectangles data source.

Test functions include CEL2VEC (micro registration and CEL2VEC comparison) for all Pad and voltage lines and balls comparison for the central balls areas (part design rule and part reference checking).

Inspect execution graph - front side.

5.2 Version II.



The inspect scan scenario uses the following tasks:

LineWidth task (inspect). Computes the width of lines (spaces) in the scanned board. Computed widths are compared to the width of lines (spaces) in the corresponding position on the reference board (the registration transformation is used to find the position of a given, computed, width report in the reference coordinate system). Every mismatch between a reference width and an on line width is recorded. The set of LWDefects is clustered and a set of rectangles around the clusters of LWDefects is produced as rectangles data source. Alternativly we may produce the set of LWDefects as points and let the Points2Rectangles task do the clustering.

Registration task. In this version the registration task produces also a list of Excess/Missing features. The list is reported as a set of EM rectangles around EM regions.

RectanglesUnifier task. Accepts various sorts of defect rectangles, cluster them and produce an, hopefully smaller set of defect rectangles.

Packer task. Uses top down rectangles and defect rectangles to define set of windows to test. If a defect window is inside a top down window then the defect rectangle is packed inside the top down window. Otherwise, a defect window is created.

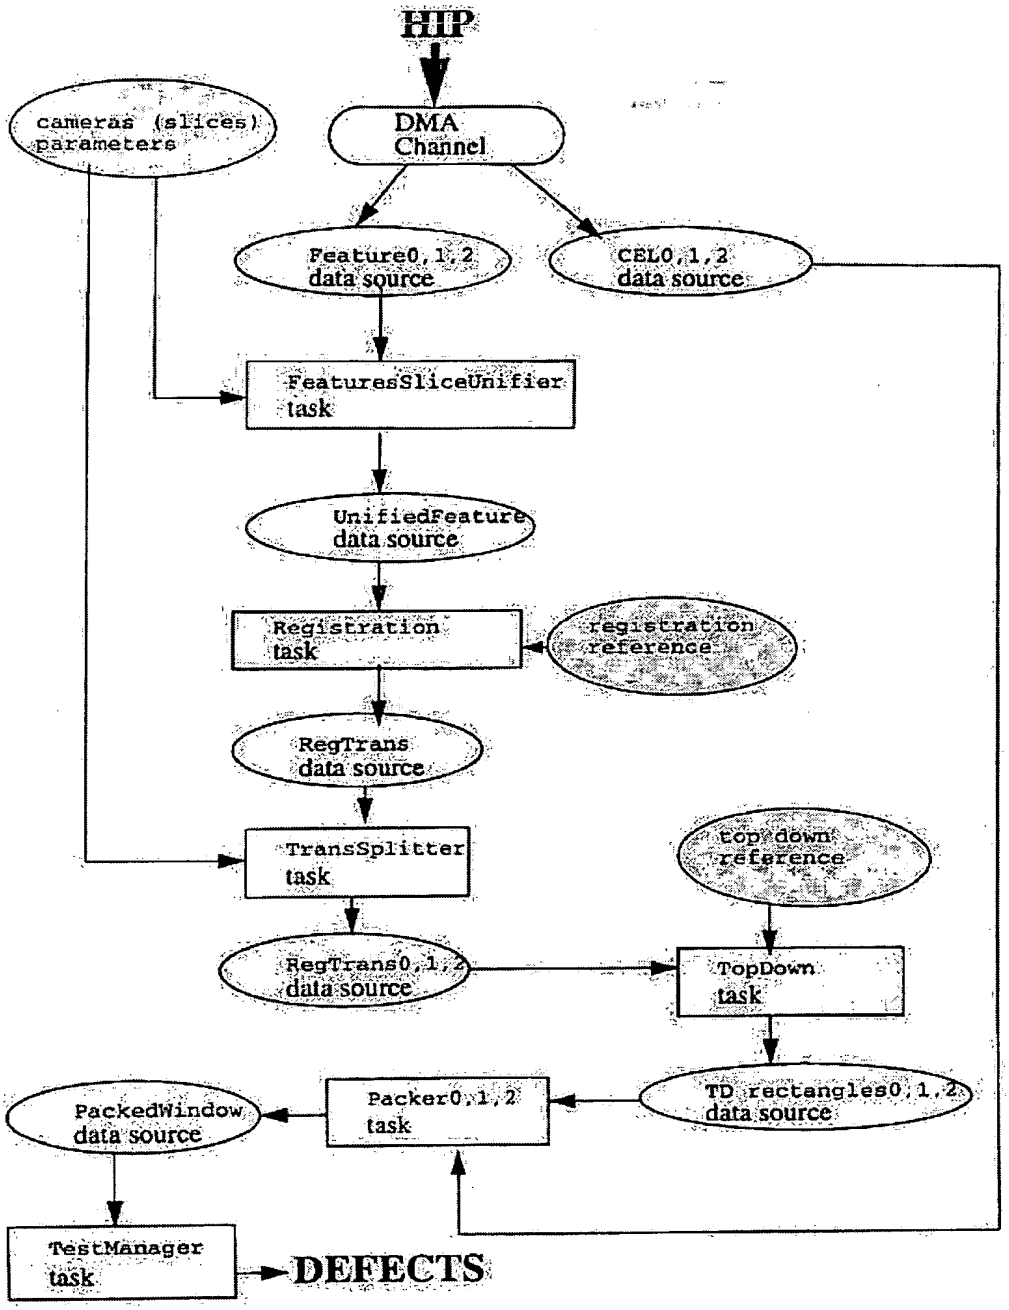
TestManager task. Responsible for the activation of test functions for the various functions. The functions are top down functions that include

- Balls window. Test function as in Version I.
- Pad. Now each pad is serrounded by a small window. That will allow us to combine (or replace) CEL2VEC by a veraity of algorithms, for example line width measurments, etc. that are better suited to find the kind of defects that the user request.
- Voltage line. Test as in Version I.
- Each of the above if also includes defect windows.

and defect window that are not included in top down windows. A possible strategy for handling a defect window is the following: If the number of different defects in the window (EM, LW, HW defects) is larger than a prescribed number, then we decide that the window is defective. Otherwise we extract reference data from data base (extraction of CELs from Dbase and vectorization) for CEL2VEC comparison, possibly followed by local line width measurment and other such stuff.

6. Inspect execution graph - back side.

6.1 Version I + II.



Registration task. Gets unified (online) features. Uses the registration reference to computes the registration transformation between the unified online coordinate system and unified reference coordinate system. Produces this transformation in the *RegTrans* data source.

TransSplitter task. Gets online (unified) to reference (unified) transformation and the camera parameters. Compute three different transformations between each slice and the reference (unified) coordinate system. Produces three data sources *RegTrans0,1,2* where RegTransi is the transformation of online slice i into the reference coordinate system.

TopDown task. Uses the top down reference (consisting of a single widow of balls) defined in the (unified) reference coordinate system. Gets the three transformations RegTrans0,1,2. Splits the balls window into three windows, one for each slice. Create three rectangles data sources, one for each slice.

PackerTask. There are three of them, each getting data for differect slice. Packing CELs inside top down rectangles for each slice.
